

2. What's Enum data type, when is it used? Name three common built-in enums.

An **Enum** is a data type that represents a fixed set of named constant values. It is used when a variable should only have one value from a predefined list.

Examples in C#:

- DayOfWeek
- ConsoleColor
- StringComparison

3. When to use String vs StringBuilder?

- Use **string** when you have a small number of changes or simple text operations because strings are **immutable**.
- Use **StringBuilder** when you need to modify or concatenate text many times, especially inside loops, because it is more **efficient**.
